Where is is used?

Web Development, Yahoo Maps, Yahoo Groups, Google, Zope Corporation, Ultraseek, Linux Weekly News, ElasticHosts Cloud Servers, Mojam.com, hunch, Shopzilla, Movieplayer.it, Multiplayer.it, Web Therapy, Battlefield 2, Crystal Space, Star Trek Bridge Commander, The Temple of Elemental Evil and Vampire: The Masquerade: Bloodlines, Civilization 4, QuArK (Quake Army Knife), Industrial Light & Magic, Walt Disney Feature Animation, HKS, Inc. (ABAQUS/CAE), RoboFog, Caligari Corporation, Blender 3D, Jasc Software, Paint Shop Pro, Altis Investment Management, ABN AMRO Bank, Treasury Systems, Bellco Credit Union, Journyx Timesheet and Resource Management Software, National Weather Service, Applied Maths, Biosoft, The National Research Council of Canada, Los Alamos National Laboratory (LANL) Theoretical Physics Division, AlphaGene, Inc., LLNL, NASA, Swedish Meteorological and Hydrological Institute (SMHI), Environmental Systems Research Institute (ESRI), Nmag Computational Micromagnetics, Objexx Engineering, Ciranova, Productivity Design Tools, PDTi's SpectaReg product is an eXtensible Memory-Mapped Register generator., Object Domain, Pardus, Red Hat, SGI, Inc., MCI Worldcom, Nokia, University of California, Irvine, Delft University of Technology, Faculty of Aerospace Engineering, Delft, Netherlands, Smeal College of Business, The Pennsylvania State University, New Zealand Digital Library, IT Certification Exam preparation, SchoolTool, Raven Bear Systems Corporation, Thawte Consulting, Advanced Management Solutions Inc., IBM, RealNetworks, dSPACE, Escom, The Tiny Company, Nxedli, WuBook

≈ 1 ≈

Readability counts.

Now is better than never.
Flat is better than nested.
Unless explicitly silenced.
Sparse is better than dense.

Beautiful is better than ugly.

Simple is better than complex.

Explicit is better than implicit.

Errors should never pass silently.
Although practicality beats purity.

Complex is better than complicated.

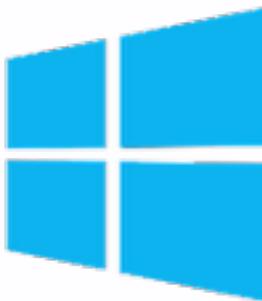

Although never is often better than *right* now.
Special cases aren't special enough to break the rules.
In the face of ambiguity, refuse the temptation to guess.
If the implementation is hard to explain, it's a bad idea

If the implementation is easy to explain, it may be a good idea

- >> highly extensible
- >> nice to read
- >> object-oriented
- >> structured

Todo es un objeto

Objects are Python's abstraction for data. All data in a Python program is represented by objects or by relations between objects. (In a sense, and in conformance to Von Neumann's model of a "stored program computer," code is also represented by objects.)

Every object has an identity, a type and a value.

[...] An object's type determines the operations that the object supports (e.g., "does it have a length?") and also defines the possible values for objects of that type.

Taken from the Python [data model reference](#)

Operaciones Aritméticas

Operación	Operador	Comentarios
Addition	<code>x + y</code>	<code>x</code> and <code>y</code> may be floats or ints
Subtraction	<code>x - y</code>	<code>x</code> and <code>y</code> may be floats or ints
Multiplication	<code>x * y</code>	<code>x</code> and <code>y</code> may be floats or ints
Division	<code>x / y</code>	If at least one of <code>x</code> and <code>y</code> is a float, then the result is also a float, be cautious when dividing integers.
Floor Division	<code>x // y</code>	<code>x</code> and <code>y</code> may be floats or ints. The result is the first integer less than or equal to the quotient
Remainder or Modulo	<code>x % y</code>	<code>x</code> and <code>y</code> must be ints. This is the remainder of diving <code>x</code> by <code>y</code> .
Exponentiation	<code>x ** y</code>	<code>x</code> and <code>y</code> must be floats or ints. This is the result of raising <code>x</code> to <code>ty</code> <code>y</code> th power.
Float conversion	<code>float(x)</code>	Convert the numeric value of <code>x</code> to a float.
Integer Conversion	<code>int(x)</code>	Convert the numveri value of <code>x</code> to an int. The decimal portion is truncated not rounded.
Absolute Value	<code>abs(x)</code>	Gives the absolute value of <code>x</code> .
Round	<code>round(x)</code>	Rounds the float, <code>x</code> , to the nearest whole number. The result is alwasy an int.

(Tabla tomada del libro de Lee)

Operaciones con Cadenas

Operación	Operador	Comentarios
Indexing	<code>x[x]</code>	Yields the x th character of the string s . The index is zero based, so $s[0]$ is the first character.
Concatenation	<code>s + t</code>	Yield the juxtaposition of the strings s and t .
Length	<code>len(s)</code>	Yields the number of characters in s .
Ordinal Value	<code>ord(x)</code>	Yields the ordinal value of a character c . The ordinal value is the ASCII code of the character.
Character Value	<code>chr(x)</code>	Yields the character that corresponds to the ASCII value of x .
String Conversion	<code>str(x)</code>	Yields the string representation of the value of x . The value of x may be an int, float, or other type of value.
Integer Conversion	<code>int(s)</code>	Yields an integer value contained in the string s . If s does not contain an integer an error will occur.
Float Conversion	<code>float(s)</code>	Yields the float value contained in the string s . If s does not contain a float an error will occur.

(Tabla tomada del libro de Lee)

¿Cómo solicitar información al usuario?

```
>>> x=raw_input("Please enter x=")
Please enter x = 
```

raw_input recibe strings, si se espera un número y quieren hacerse operaciones aritméticas, debe entonces convertirse en un objeto de tipo numérico.

```
>>> x=float(raw_input("x="))
x=10.2
>>> print x + 2
12.2
```

Si se espera que el usuario entregue una lista (con elementos separados por espacios en blanco) usar raw_input seguido the el método split aplicado sobre la cadena recibida, lo cual produce una lista que contiene sus elementos.

```
>>> theList=raw_input("Please enter a list of things: ")
Please enter a list of things: gato 2 3 4
>>> theSlist = theList.split()
>>> print theSlist
['gato', '2', '3', '4']
```

```
if condition:  
    thing_to_do1  
    thing_to_do2
```

If ... else

```
if condition:  
    thing_to_do1  
    thing_to_do2  
else:  
    other_thing1  
    other_thing2
```

¡La indentación es esencial!

lf

While

While

```
while condition:  
    thing_to_do1  
    thing_to_do2
```

```
# This code prints all ordered pairs of  
# integers with the integers ranging  
# from 1 to 10. Look with caution at the  
# usage of indentation  
j = 1  
while j <= 10:  
    i = 1  
    while i <= 10:  
        print "{" + str(j) + ", " + \  
              str(i) + "}",  
        i += 1  
    j += 1
```

Listas

```
>>> lista = ["uno", "dos", "tres", 2]
```

Los elementos de una lista se dan entre corchetes cuadrados y sus elementos pueden ser de diferente tipo.

```
>>> print lista[0]
uno
>>> lista[-1] += 1
print lista
['uno', 'dos', 'tres', 3]
>>> lista.append(4)
print lista
['uno', 'dos', 'tres', 3, 4]
```

El n-ésimo elemento de la lista se invoca ingresando `lista[n-1]`.

Se pueden usar índices negativos para elegir elementos contando desde el último elemento, por ejemplo `lista[-1]` hace referencia al último elemento.

Para añadir elementos a una lista se invoca el método `append` sobre la misma, por ejemplo **lista.append(4)** toma una lista y le añade al final el número 5.

Otros métodos que pueden invocarse sobre una lista: **pop** (quitar el último elemento), **reverse** (invertir el orden), **extend** (como append pero con listas).

lista[start:stop:step] toma los elementos de la lista comenzando en el índice *start* terminando en *stop* en incrementos *step*, por ejemplo `range(100)[10:50:2]` produce una lista con todos los números pares entre 10 y 50.

for

```
for i in range(1,10):
    thesquare = i**2
    print str(i)+"^2="+str(thesquare)
```

```
1^2=1
2^2=4
3^2=9
4^2=16
5^2=25
6^2=36
7^2=49
8^2=64
9^2=81
```

```
for x in range(10):
    y = 2*x
    if x == 3:
        break
    print y
```

```
0
2
4
```

Use **break** to break a
for loop.

```
emptyS=""
for s in "Juan David Lizarazo":
    emptyS = s + emptyS
print emptyS
ozaraziL divaD nauJ
```

It is possible to iterate
over strings

```
for i in iterableObj:
    todo1
    todo2
    todo3
    todo4
```

Iterable Objects

strings,
lists.

range(n) gives a
list of integers
from 0 to n-1

range(a,b) gives a
list of integers
from a to b-1
